

# **PET MEDS SPAWN MITES**

## **THE USE OF PET MEDS MAY LEAD TO PARASITE INFESTATIONS**

**PUBLIC SERVICE ANNOUNCEMENT:** Mite infestations of pets, structures and subsequently a human host have increased dramatically in the last few years. What was once viewed as a phenomenon now appears to be a everyday occurrence. The application of PET MEDS or commonly known Flea or Spot Drops to the neck of your pet often result in a internal skin parasite issue in your pet and yourself. Fiprinol, Permethrins and other toxins wicked systemically into the animals blood stream result in the creation of a compromised immune system prohibiting the pets body from resisting attack from these wicked internal parasites. Once identified as a host, the mites will attack the dog or cat with overwhelming vigor. Additional mite populations are propagated and in a short period of time the animal and the structure is the recipient of a full blown mite infestation. The COLUMBELLA MITE is a microscopic parasite found in the air and on all surfaces. They are introduced to the body through the lungs and subsequently into the blood stream where they are destroyed by the liver as the blood is filtered through the bodies organs. When the pets immune system is compromised with the PET MEDS its filtering organs cease to function properly and subsequently the blood carried mite will migrate into the epidermal layer of the skin through the blood stream capillaries. When the animal can no longer support the mite population it is hosting, the parasite will adopt another host within the structure. This is normally the care giver or the closest person to the animal. Often this is a chemically imbalanced or less healthy individual that may itself have a over-reactive or compromised immune system. Once infested with the parasite a persons normal life style is totally disrupted. Constant biting and itching sensations and subsequent eruptions of the skin become debilitating and difficult to endure. The mites will attack the individual from the inside and the outside. Visual contact is next to impossible and medical diagnosis from the majority of the medical community is wrongfully that of parasitic psychosis. Treatment requires fogging or fumigation of the structure and applications of BEST YET MITICIDE, a low molecular weight silicone fluid carrier and modified essential oil of the juniperus virginiana tree (cedar) to the human and animals body. Internal relief can be obtained with properly dosed regiments of Stromectol, a prescription drug used for eradication of internal parasites. Reduction of the mite population within the structure and surrounding areas and on the human and animals body surface is the first step in elimination of this horrible dilemma. Once this is accomplished and the intake of the parasite is minimized, the mammals body will resume its normal eradication of the COLUMBELLA mite. PET MEDS should be immediately discontinued from any animal health protocols practiced. Immune system elevating foods and vitamins should be utilized.
